# Package 'StageWise'

May 27, 2024

```
Title Two-stage analysis of multi-environment trials for genomic selection and GWAS
Version 1.08
Author Jeffrey B. Endelman
Maintainer Jeffrey Endelman <endelman@wisc.edu>
Description Fully efficient, two stage analysis of multi-
      environment trials, including directional dominance and multi-trait genomic selection

blup BLUP

# Description

BLUP

# Usage

```
blup(data, geno = NULL, what, index.coeff = NULL, gwas.ncore = 0L)
```

# Arguments

data	one object, or list of objects, of class_prep from blup_prep
geno	object of class_geno from read_geno
what	One of the following: AV, BV, GV, AM, DM. See Details.
index.coeff	named vector of index coefficients for the locations or traits
gwas.ncore	Integer indicating number of cores to use for GWAS (default is 0 for no GWAS).

blup\_prep 3

### **Details**

The argument what takes 5 possible values: "AV" (additive value), "BV" (breeding value), "GV" (genotypic value), "AM" (additive marker effect), and "DM" (dominance marker effect). "Values" refer to predictions for individuals, as opposed to markers. Predicted values include the average fixed effect of the environments, whereas predicted marker effects do not. Argument index.coeff is a named vector (matching the names of the locations or traits), and the values are interpreted for standardized traits.

When multiple objects of class\_prep are used for data, they must be based on the same marker data and genetic model. Also, reliabilities are not computed.

### Value

Data frame of BLUPs

blup_prep	Prepare data for BLUP	

### **Description**

Prepare data for BLUP

### Usage

```
blup_prep(data, vcov = NULL, geno = NULL, vars, mask = NULL, method = NULL)
```

### **Arguments**

data	data frame of BLUEs from Stage 1
vcov	list of variance-covariance matrices for the BLUEs
geno	object of class_geno from read_geno
vars	object of class_var from Stage2
mask	(optional) data frame with possible columns "id", "env", "trait"
method	(optional) "MME", "Vinv", NULL (defaut). see Details

### Details

The method argument can be used to control how the linear system is solved. "MME" leads to inversion of the MME coefficient matrix, while "Vinv" leads to inversion of the overall var-cov matrix for the response vector. If NULL, the software uses whichever method involves inverting the smaller matrix. If the number of random effects (m) is less than the number of BLUEs (n), "MME" is used.

For the multi-location model, if all of the environments for a location are masked, the average of the other locations is used when computed average fixed effects.

# Value

```
Object of class_prep
```

4 class\_genoD-class

class\_geno-class

S4 class for marker genotype data

### **Description**

S4 class for marker genotype data

### **Slots**

```
ploidy ploidy
map Marker map positions
coeff Coefficients of the marker effects (dim: indiv x marker)
scale Scaling factor between markers and indiv
G Additive relationship matrix (from markers and potentially also pedigree)
eigen.G list of eigenvalues and eigenvectors
```

class\_genoD-class

S4 class for marker genotype data with dominance

# Description

S4 class for marker genotype data with dominance

# **Slots**

```
ploidy ploidy
map Marker map positions

coeff Coefficients of the additive marker effects (dim: indiv x marker)
scale Scaling factor between markers and indiv for additive effects
G Additive relationship matrix (from markers and potentially also pedigree)
eigen.G list of eigenvalues and eigenvectors for G

coeff.D coefficients of the dominance marker effects (dim: indiv x marker)
scale.D Scaling factor between markers and indiv for dominance effects
D Dominance relationship matrix
eigen.D list of eigenvalues and eigenvectors for D

Fg genomic inbreeding coefficient (based on dominance)
```

class\_prep-class 5

class\_prep-class

S4 class to prepare for blup

# **Description**

S4 class to prepare for blup

### **Slots**

```
id genotype identifiers
ploidy ploidy
var.u variance of random effects
var.uhat variance of BLUPs
avg.env average fixed effect of the environments
heterosis regression coefficients for inbreeding
fixed.marker fixed marker effects
B var-cov matrix for fixed effects
random random effect estimates
geno1.var first var-cov matrix from class_var
geno2.var second var-cov matrix from class_var
model model from class_var
```

class\_var-class

S4 class for variances

# **Description**

S4 class for variances

### **Slots**

```
geno1 first genetic effect
geno2 second genetic effect
model 0=no markers, 1=add, 2=add+g.resid, 3=add+dom
resid residual
diagG average diagonal element of the G matrix
diagD average diagonal element of the D matrix
vars variances for reporting
B var-cov matrix of fixed effects for gain
fix.eff.marker names of fixed effect markers
```

6 dominance

corr Trait correlations

# **Description**

Trait correlations

# Usage

```
corr(vars, traits = NULL, effect = NULL)
```

# **Arguments**

vars object of class\_var from Stage2

traits pair of traits effect name of effect

# **Details**

Use either the argument traits or effect, not both. Using traits leads to a partitioning of the total correlation between those two traits, based on path analysis, assuming no correlation between the effects of the Stage 2 model. Using effect displays the correlation between all traits for that effect. Use the summary command to see the names of the possible effects.

# Value

matrix

dominance

Report dominance parameters

# **Description**

Report dominance parameters

# Usage

```
dominance(params, digits = 2, index.coeff = NULL, gamma = 0)
```

# Arguments

params list returned by Stage2

digits number of digits for rounding

index.coeff merit index coefficients

gamma contribution of non-additive values for genetic merit

gain 7

### **Details**

The dominance variance (Vd) and baseline heterosis (b) are quantified relative to additive variance (Va) and std. dev. (SDa), respectively. For single traits, the estimate and SE of the ratios are calculated based on the delta method (Rice 2007, p. 162-166). For a multi-trait model, the result is just the ratio of the estimates, with index.coeff specifying the coefficients of the standardized true values (see also blup) and gamma specifying the relative weight for non-additive to additive genetic merit (see also gain).

### Value

data frame with estimates and SE

### References

Rice JA (2007) Mathematical Statistics and Data Analysis, 3rd ed. Duxbury, Pacific Grove.

gain Genetic gain

# **Description**

Genetic gain calculations

# Usage

```
gain(
  input,
  merit = NULL,
  desired = NULL,
  restricted = NULL,
  traits = NULL,
  gamma = NULL,
  solver = "ECOS",
  ...
)
```

### **Arguments**

input	either object of class_prep or quad.mat returned by this function
merit	named vector of merit coefficients, in genetic standard deviation units
desired	named vector of desired gains, in genetic standard deviation units
restricted	data frame of restricted traits, see Details
traits	optional vector with exactly 2 trait names, to plot elliptical response
gamma	contribution of non-additive values for genetic merit
solver	name of convex solver (default is "ECOS")

8 gwas\_threshold

#### **Details**

Either merit or desired can be used, not both. The former specifies the relative contribution of each trait to genetic merit, while the latter specifies the relative desired gain in genetic standard deviation units. All traits must be specified. Optional argument restricted is a data frame with columns "trait" and "sign", where the options for sign are "=",">","<", representing equal to zero, non-negative, and non-positive. When desired is used, the restricted argument is ignored.

The argument gamma controls the definition of genetic merit. (See notation in the journal publication.) The default is NULL, which implies breeding values. For purely additive values, use gamma = 0. For total genotypic value, use gamma = 1.

Note that this function assumes a selection index of BLUPs, not phenotypes.

### Value

List containing

quad.mat quadratic matrix for the ellipsoid

**plot** ellipse plot

table data frame with the response and index coefficients for all traits

gwas\_threshold

Compute GWAS discovery threshold

### **Description**

Compute GWAS discovery threshold

### Usage

```
gwas_threshold(geno, alpha = 0.05, exclude.chrom = NULL, n.core = 1)
```

### **Arguments**

geno object of class\_geno

alpha genome-wide significance level

exclude.chrom chromosomes to exclude n.core number of cores to use

### **Details**

Uses a Bonferroni-type correction based on an effective number of markers that accounts for LD (Moskvina and Schmidt, 2008).

# Value

-log10(p) threshold

# References

Moskvina V, Schmidt KM (2008) On multiple-testing correction in genome-wide association studies. Genetic Epidemiology 32:567-573. doi:10.1002/gepi.20331

inbreeding 9

inbreeding

Genomic inbreeding coefficient

# Description

Genomic inbreeding coefficient

# Usage

```
inbreeding(geno)
```

# **Arguments**

geno

object of class\_geno

### **Details**

Under the additive model, the inbreeding coefficient comes from the diagonal elements of the G matrix according to F = (G-1)/(ploidy-1). For dominance, the inbreeding coefficient is the scaled row-sum of the dominance coefficient matrix.

### Value

data frame with F[G] and (when dominance is present) F[D]

manhattan\_plot

Create Manhattan plot

# **Description**

Create Manhattan plot

# Usage

```
manhattan_plot(data, chrom = NULL, thresh = NULL, rotate.label = FALSE)
```

# Arguments

data frame with columns for marker, chrom, position, and score

chrom optional, to plot only one chromosome

thresh optional, to include horizontal line at discovery threshold

rotate.label TRUE/FALSE whether to rotate x-axis labels to be perpendicular

# **Details**

Assumes position in bp

# Value

ggplot2 object

10 quantile

predict

Predict individual values from marker effects

# Description

Predict individual values from marker effects

# Arguments

```
object of class_geno
marker.effects data frame with columns "marker" and "effect"
```

### **Details**

Use the blup function with what="AM" or "DM" to generate the data frame for marker.effects.

### Value

data frame with columns "id" and "value"

quantile

G matrix quantile

# Description

G matrix quantile

# Arguments

```
x object of class_geno
prob probability
```

# **Details**

Unlike the S3 method, prob must have length = 1

# Value

data frame with the quantile of the G matrix coefficients for each id

read\_geno 11

read\_geno

Read marker genotype data

### **Description**

Read marker genotype data

### Usage

```
read_geno(
  filename,
  ploidy,
  map,
  min.minor.allele = 5,
  w = 1e-05,
  ped = NULL,
  dominance = FALSE
)
```

### **Arguments**

filename Name of CSV file with marker allele dosage

ploidy 2,4,6,etc. (even numbers)

map TRUE/FALSE

min.minor.allele

threshold for marker filtering (see Details)

w blending parameter (see Details)

ped optional, pedigree data frame with 3 or 4 columns (see Details)

dominance TRUE/FALSE whether to include dominance covariance (see Details)

# **Details**

When map=TRUE, first three columns of the file are marker, chrom, position. When map=FALSE, the first column is marker. Subsequent columns contain the allele dosage for individuals/clones, coded 0,1,2,...ploidy (fractional values are allowed). The input file for diploids can also be coded using -1,0,1 (fractional values allowed). Additive coefficients are computed by subtracting the population mean from each marker, and the additive (genomic) relationship matrix is computed as G = tcrossprod(coeff)/scale. The scale parameter ensures the mean of the diagonal elements of G equals 1 under panmictic equilibrium. Missing genotype data is replaced with the population mean.

G can be blended with the pedigree relationship matrix (A) by providing a pedigree data frame in ped and blending parameter w. The blended relationship matrix is H = (1-w)G + wA. The first three columns of ped are id, parent1, parent2. Missing parents must be coded NA. An optional fourth column in binary (0/1) format can be used to indicate which ungenotyped individuals should be included in the H matrix, but this option cannot be combined with dominance. If there is no fourth column, only genotyped individuals are included. If a vector of w values is provided, the function returns a list of class\_geno objects.

If the A matrix is not used, then G is blended with the identity matrix (times the mean diagonal of G) to improve numerical conditioning for matrix inversion. The default for w is 1e-5, which is

12 remove\_spatialtrend

somewhat arbitrary and based on tests with the vignette dataset. The D matrix is also blended with the identity matrix using 1e-5 for numerical conditioning.

When dominance=FALSE, non-additive effects are captured using a residual genetic effect, with zero covariance. If dominance=TRUE, a (digenic) dominance covariance matrix is used instead.

The argument min.minor.allele specifies the minimum number of individuals that must contain the minor allele. Markers that do not meet this threshold are discarded.

#### Value

Variable of class class\_geno.

remove\_spatialtrend Remove spatial trend

### **Description**

Removes spatial trend to prepare for multi-trait Stage 1

### Usage

```
remove_spatialtrend(filename, traits, spline, effects = NULL)
```

### **Arguments**

filename Name of CSV input file

traits trait names

spline vector of variable names for 2D spline with SpATS

effects data frame specifying other effects in the model (see Details)

### **Details**

SpATS used to remove 2D spatial trend for each field experiment, labeled with column 'expt' in the input file. Genotype labels are in column 'id' and modeled as i.i.d random effect. Argument effects is used to specify other i.i.d. effects besides genotype and has three columns: name, fixed, factor. The "name" column is a string that must match a column in the input file. The fixed column is a logical variable to indicate whether the effect is fixed (TRUE) or random (FALSE). The factor column is a logical variable to indicate whether the effect is a factor (TRUE) or numeric (FALSE).

Argument traits is a character vector of trait names. Single-trait analyses are performed for each trait, and the results are combined in the output.

### Value

Data frame with adjusted phenotypes

Stage1 13

Stage1	Stage 1 analysis of multi-environment trials	
Stage1	Stage 1 analysis of multi-environment trials	

# **Description**

Computes genotype BLUEs for each experiment

# Usage

```
Stage1(
  filename,
  traits,
  effects = NULL,
  solver = "asreml",
  spline = NULL,
  silent = TRUE,
  workspace = c("500mb", "500mb"),
  max.iter = 30
)
```

### **Arguments**

filename	Name of CSV file
traits	trait names (see Details)
effects	data frame specifying other effects in the model (see Details)
solver	one of the following: "asreml", "spats"
spline	vector of variable names for 2D spline with SpATS
silent	TRUE/FALSE, whether to suppress REML output
workspace	memory limits for ASRreml-R
max.iter	maximum number of iterations for ASRreml-R

### **Details**

The input file must have one column labeled "id" for the individuals and one labeled "env" for the environments. The data for each environment are analyzed independently with a linear mixed model. Although not used in Stage1, to include a genotype x location effect in Stage2, a column labeled "loc" should be present in the input file.

Argument effects is used to specify other i.i.d. effects besides genotype and has three columns: name, fixed, factor. The "name" column is a string that must match a column in the input file. The fixed column is a logical variable to indicate whether the effect is fixed (TRUE) or random (FALSE). The factor column is a logical variable to indicate whether the effect is a factor (TRUE) or numeric (FALSE).

Argument solver specifies which software to use for REML. Current options are "asreml" and "spats". For "spats", the argument spline must be a vector of length two, with the names of the x and y variables (respectively) for the 2D spline.

The heritability and residuals in the output are based on a random effects model for id.

Missing response values are omitted for single-trait analysis but retained for multi-trait analysis (unless both traits are missing), to allow for prediction in Stage 2.

14 Stage2

Argument workspace is a vector of length two containing the workspace and pworkspace limits for ASReml-R, with default values of 500mb. If you get an error about insufficient memory, try increasing the appropriate value (workspace for variance estimation and pworkspace for BLUE computation).

For multiple traits, only "asreml" is supported, and only the BLUE model is run, so the returned object does not contain H2.

If the input file has a column "expt", this allows for the use of separate spatial models for multiple experiments within an environment (only for single trait): each experiment is first analyzed separately, and then the BLUEs from all experiments per env are jointly analyzed to compute a single BLUE per env. The estimation errors from each experiment are propagated into the multi-expt model using ASReml-R. The situation is different with multi-trait analysis, as all experiments are analyzed jointly per env, with a fixed effect for expt but a common residual model. Any additional cofactors (e.g., block) that are nested within expt need to be explicitly nested!

### Value

List containing

blues data frame of BLUEs

vcov list of variance-covariance matrices for the BLUEs, one per experiment (env)

fit data frame with broad-sense H2 (plot basis) and/or AIC

**resid** For single trait, list of diagnostic plots and data frame of residuals. For multi-trait, list of resid var-cov matrices.

Stage2

Stage 2 analysis of multi-environment trials

### **Description**

Stage 2 analysis of multi-environment trials

# Usage

```
Stage2(
  data,
  vcov = NULL,
  geno = NULL,
  fix.eff.marker = NULL,
  silent = TRUE,
  workspace = "500mb",
  non.add = "g.resid",
  max.iter = 20,
  covariates = NULL,
  pairwise = FALSE
)
```

Stage2 15

### **Arguments**

data frame of BLUEs from Stage 1 (see Details)

vcov named list of variance-covariance matrices for the BLUEs

geno output from read\_geno

fix.eff.marker markers in geno to include as additive fixed effect covariates silent TRUE/FALSE, whether to suppress ASReml-R output workspace Memory limit for ASRreml-R variance estimation non.add one of the following: "none", "g.resid", "dom" max.iter maximum number of iterations for asreml

covariates names of other covariates in data

pairwise TRUE/FALSE should multi-trait analysis proceed pairwise

### **Details**

Stage 2 of the two-stage approach described by Damesa et al. 2017, using ASReml-R for variance component estimation. The variable data has three mandatory column: id, env, BLUE. Optionally, data can have a column labeled "loc", which changes the main effect for genotype into a separable genotype-within-location effect, using a FA2 covariance model for the locations. Optionally, data can have a column labeled "trait", which uses an unstructured covariance model. The multi-location and multi-trait analyses cannot be combined. Missing data are allowed in the multi-trait but not the single-trait analysis. The argument geno is used to partition genetic values into additive and non-additive components. Any individuals in data that are not present in geno are discarded.

The argument vcov is used to partition the macro- and micro-environmental variation, which are called GxE and residual in the output. vcov is a named list of variance-covariance matrices for the BLUEs within each environment, with id for rownames (single trait) or id:trait. The order in vcov and data should match. Both data and vcov can be created using the function Stage1.

Because ASReml-R can only use relationship matrices defined in the global environment, this function creates and then removes global variables when either vcov or geno is used. By default, the workspace memory for ASReml-R is set at 500mb. If you get an error about insufficient memory, try increasing it. ASReml-R version 4.1.0.148 or later is required.

The covariates option is only available for single trait/loc analysis.

Argument pairwise was added in package version 1.04, which specifies that multi-trait analysis is performed as multiple bivariate analyses, which often converges better. The returned object is a list of the results from the bivariate analyses, as well as "vars" for all traits, which is needed for blup\_prep.

### Value

List containing

aic AIC

vars variance components for blup\_prep, as variable of class class\_var

params Estimates and SE for fixed effects and variance components

random Random effect predictions

loadings scaled loadings for the FA2 multi-loc model

### References

Damesa et al. 2017. Agronomy Journal 109: 845-857. doi:10.2134/agronj2016.07.0395

16 uniplot

summary.var Disp	lays variances and correlations
------------------	---------------------------------

### **Description**

Displays variances and correlations

### **Arguments**

object of class\_var

digits number of digits for rounding

index.coeff merit index coefficients

gamma contribution of non-additive values for genetic merit

### **Details**

For a single trait, the 'var' output is a data frame with two columns of information for the various effects: the first is the variance and the second is the proportion of variance explained (PVE), excluding the environment effect. For multiple locations or traits, the 'cor' output is the correlation matrix for additive effects (does not include fixed effect markers). For multiple traits, the variance and PVE results are returned as separate data frames, unless index. coeff is used to create an index.

The index.coeff are the coefficients of the standardized true values (see also blup). The argument gamma is the relative weight for non-additive to additive genetic merit (see also gain).

# Value

List output that varies depending on the situation (see Details)

uniplot Uniplot for multi-location models

# **Description**

Displays scaled loadings of the FA2 model

# Usage

```
uniplot(loadings, nudge = 0.1)
```

# **Arguments**

loadings scaled factor loadings, from Stage2.

nudge distance to nudge labels

# **Details**

The squared radius for each point is the proportion of genetic variance explained by the latent factors. For points on the unit circle, the cosine of the subtended angle equals the correlation.

wheat.data 17

### Value

ggplot2 object

wheat.data

Genomic prediction from secondary traits in wheat

# **Description**

Canopy temperature (CT) measurements collected during grain fill; used for genomic prediction of grain yield (GY) in wheat. Data come from the drought and extreme drought environments of Rutkoski et al. (2016). The CT phenotype was dated 3/7/2014. Stage 1 BLUEs were computed using rep(trial) as a random effect.

# Usage

data(wheat)

### **Format**

wheat.geno is object of class\_geno. wheat.blues and wheat.vcov are output from Stage1.

### References

Rutkoski et al. (2016) G3 (Bethesa) 6:2799–2808. https://doi.org/10.1534/g3.116.032888
